Abstract

In this paper, the output regulation problem is investigated, which consists of building a controller to asymptotically steer the output of a saturated linear systems to a given reference signal despite external disturbances. Particularly, for saturated systems subject to periodically time-dependent exosystem, a K-step asymptotically regulatable region was characterized by a set of all the initial states of the plant and the exosystem. Improved internal model principles were constructed on the balance between the state convergence rate and the control of all the initial state. Finally, a state feedback controller was designed to ensure exponential output regulation in the regulatable region with disturbance rejection. Simulation examples were given to illustrate the effectiveness of proposed method. The results show these systems can go into stable rapidly and periodically.

Keywords: saturation constraint, output regulation, internal model principles, feedback controller

1 Introduction

Reference signals tracking is an important subject in systems theory. Regulation theory provides a framework that allows the analysis and design of controllers capable of achieving the tracking of references, even in the presence of disturbances.

Saturation constraint is a kind of nonlinear constraint in many practical conditions. This addresses the problem of designing a feedback controller for an uncertain plant so that the closed loop system is internally stable and the output of the closed-loop system can asymptotically track a class of reference inputs in the presence of a class of disturbances. Francis and Wonham [1, 2] proposed the internal mode principle, which aims to convert the output regulation problem of a given plant into a stabilization problem of an augmented system composed of the given plant and a well defined dynamic compensator.

For the cases where the exogenous signals are constant, Francis [2] designed a linear robust regulator based on the linear approximation of the plant can solve the local structurally stable output regulation problem for the nonlinear plant. Huang and Rugh [3] made a further work and put the solution to nonlinear plant under normal disturbance. Self-Adaptive method and optimal feedback control [4-7] were used in solving the problem of globe robust output regulation for nonlinear system disturbed by uncertain exogenous signals. Disturbance suppression of a class of nonlinear systems was studied in [8-10]. However, it should be pointed that most of the studies are carried with semi-stable exosystem, the problem of output regulation for saturated systems under the action of nonlinear exosystem has received relatively less attention. The few works motivate our current research are [11-14]. In [11], robust adaptive constrained motion tracking control methodology was derived for bounded nonlinear effects and external disturbance within the closed-loop system. Output regulation for periodic signal of constrained MIMO system subject to actuators saturated is studied in [12]. To exact output regulation for Takagi-Sugeno (T–S) fuzzy models, [13] considered the fuzzy model as a special class of linear time-varying systems, existence conditions are rigorously derived.

In the nonlinear case, the inclusion of an internal model was proved to be a necessary condition to guarantee robustness with respect to parameter variations. This internal model is obtained as an immersion of the exosystem into a dynamical system which generates all the possible steady-state inputs for any admissible parameter variation [14].

The steady-state zero-error manifold is a centre manifold, which becomes invariant by the effect of the steady-state input. Therefore, the regulation process can be understood as follows: 1) The stabilizer is responsible for taking the states of the plant toward the steady-state zero-error manifold, reducing this way the tracking error; 2) the steady-state input keeps the states of the plant on the steady-state zero-error manifold, this way achieving the exact tracking of the reference signals. Then, regulation problem consists in finding both the steady state zero-error manifold and the steady-state input [15]. See Figure 1 for the graphical representation of the nonlinear regulation problems.

In this paper we consider the regulation problem of linear system subject to actuator saturation under the action of nonlinear exosystem. Based on our earlier results mentioned in [16], a simple feedback controller was achieved by a stabilizing law for output regulation of linear system with input constrains.

Under the action of a nonlinear exosystem action, the problem to be addressed in this paper is the following: (1) Characterize of the regulatable region. The first task of this paper is to characterize the set of initial conditions for which there exist admissible controls to keep the state bounded and to drive the tracking error to 0 asymptotically. (2) Design of constrained state feedback controller. Find a state feedback law and construct the state controller.

2 Problem statement and preliminaries

Consider the system

\[
\begin{align*}
x(k+1) &= Ax(k) + Bu(k) + P\omega(k) \\
e(k) &= Cx(k) + Q\omega(k) \\
\omega(k+1) &= S\omega(k)
\end{align*}
\]

where \( A \in \mathbb{R}^{n \times n}, B \in \mathbb{R}^{n \times m}, P \in \mathbb{R}^{n \times k}, C \in \mathbb{R}^{m \times n}, Q \in \mathbb{R}^{m \times k} \). The first plant describes a plant, with state \( x \in \mathbb{R}^n \), input \( u \in \mathbb{R}^m \) and \( ||u||_\infty \leq 1 \), subject to the effect of disturbance represented by \( P\omega(k) \). The error between the actual output \( Cx(k) \) and a reference signal \( Q\omega(k) \) is defined as \( e(k) \) by the second equation. The third equation describes the exosystem with state \( \omega \in \mathbb{R}^r \) and \( S \in \mathbb{R}^{m \times r} \).

Due to the constraint input, it’s well known that the initial state of the plant and exosystem can not be in the whole space. We should characterize the set of all initial states \( (x_0, \omega_0) \in \mathbb{R}^{n+r} \), on which the problem of constrained output regulation is solvable. This set is called regulatable region. If we can construct a state feedback law, \( u = \phi(x, \omega) \), \( ||\phi(x, \omega)||_\infty \leq L \) and \( \phi(0, 0) = 0 \), by which following conditions are satisfied:

A. Plant \( x(k+1) = Ax(k) + B\phi(x,0) \) is asymptotically stable on the equilibrium point \( x=0 \).

B. For all initial states \( (x_0, \omega_0) \in \mathbb{R}^{n+r} \) in regulatable region, the close-loop system has \( \lim_{k\to\infty} x_e(k) = 0 \).

To begin with, some necessary assumptions are made:

A1. The pair \((A, B)\) is stabilizable.

A2. \( S \) has all its eigenvalues on the unit circle and diagonalizable.

A3. \( \begin{bmatrix} C & Q \\ A & P \end{bmatrix} \) is measurable.

A4. There exist matrices \( \Pi \) and \( \Gamma \) solve the linear matrix equation

\[
\begin{bmatrix} \Pi S \end{bmatrix} = \begin{bmatrix} \Pi \Pi \end{bmatrix} + \begin{bmatrix} B \Gamma + P \end{bmatrix} \quad \text{and} \quad 0 = \begin{bmatrix} \Pi \end{bmatrix} + Q \begin{bmatrix} \Pi \end{bmatrix},
\]

(2)

In this paper, we focus on two kinds of nonlinear external disturbance: the square wave and triangle wave. The square wave is discontinuous and underivable, can be described as \( \omega(k+1) = S\omega(k), S \) is an unit matrix. If \( S \) is an unit matrix and \( \omega(k) \neq 0 \) for all \( k \geq 0 \), then the control law is called a state feedback controller.

Let \( \omega(0) = [m \ m]^T \), when \( k = nT/2 \) \((n = 0, 1, 2 \ldots)\), \( \omega(k) = (1)^n\omega(0) \). There are two step signals of different amplitude in one cycle, and the step signal is linear. If the period \( T \) is long enough, the action of exosystem can be viewed as with constant disturbance that works alternatively. Review our earlier works in [16], it is possible to design an easily implementable state controller to make the close loop system stable asymptotically, simulation results are shown in section 5.

Detailed study on output regulation problem is focus on the influence of periodic triangle wave.

3 The regulatable region

The triangle wave is continuous but underirable. Triangle with period \( T \) and amplitude \( m \) is described as follows, where \( \omega(0) = 0 \):

\[
\omega(k+1) = \begin{cases} \omega(k) + a & nT \leq k < nT + T/2 \\ \omega(k) - a & nT + T/2 \leq k < (n+1)T \end{cases} \quad n = 0, 1, 2, 3 \ldots
\]

(3)

at the equilibrium point, let \( u(k) = \Gamma\omega(k) + Ga \), \( x(k) = \Pi\omega(k) \).

By (1)

\[
e(k) = Cx(k) + Q\omega(k) = CTI\omega(k) + Q\omega(k) = 0 .
\]

(4)

If \( B \) has full row rank, then \( G \) exists made:

\[
\begin{bmatrix} \Pi = BG & nT \leq k < nT + T/2 \\ \Pi = -BG & nT + T/2 \leq k < (n+1)T \end{bmatrix} \quad n = 0, 1, 2, 3 \ldots
\]

(5)
Due to $\omega(k) \neq 0$, by (3), (6), the internal mode of triangle wave action is represents as (7):

$$\begin{align*}
\Pi &= AP + BT + P \\
\text{CTI} + Q &= 0
\end{align*}$$

(7)

Consider system (1), a control signal $u$ is said to be admissible if $||u(k)||_{\infty} \leq 1$.

**Definition 3.1:** For some $K > 0, (x_0, \omega_0) \in R^m \times R^p$ is said to be $K$-step regulatable if there exists an admissible $u$ makes $e(k) \equiv 0$. The set of all regulatable pairs $(x_0, \omega_0)$ is $K$-step regulatable region, denoted by $R_x(K)$.

According to classical regulation theory, there exists matrix $\Pi \in R^{p \times q}$ and matrix $\Gamma \in R^{n \times r}$ makes the equation (7) solvable, meanwhile, (7) is a zero-state equation which describes the equilibrium point as

$$u(k) = \Gamma \omega(k) + Ga, \quad x(k) = \Pi \omega(k), \quad u(k) = \omega(k) + Ga,$$

where $e(k) \equiv 0$. Due to the restriction that $||u(k)||_{\infty} \leq 1$, $e(k)$ will go to zero asymptotically at the equilibrium point only if

$$\sup_{k \geq 0} ||x(k)||_{\infty} \leq 1.$$  

(9)

Thus, the exosystem initial conditions corresponding to this equilibrium point are restricted in the compact set

$$W_0 = \{\omega_0 \in R^p : ||aT/2 + Ga||_{\infty} \leq 1, \forall k \geq 0\}.$$  

(10)

**Definition 3.2:** For some $K > 0$, a state $x_0$ is said to be null controllable if there exists an admissible $u$ makes the system state transforms from $x(0) = x_0$ and satisfies $\lim_{k \to \infty} x(k) = 0$. The set of all the null controllable region $x_0$ is null controllable region, denoted by $C_x(A, B)$. Specially, the set of null controllable region is called $K$-step null controllable region when $x(K) = 0$, denoted by $C_K(A, B)$.

By similarity transformation, we may assume $A = A_1 \begin{bmatrix} A_2 & 0 \\ 0 & A_2 \end{bmatrix} \in R^{n \times n} \times \{s \geq \lambda \}n \times n, \quad B = B_1 \begin{bmatrix} B_2 \\ B_2 \end{bmatrix} \in R^{n \times r} \times n \times r$, where $A_1$ has all eigenvalues inside or on the unit circle and $A_2$ has all eigenvalues outside the unit circle. So, the null controllable region $C(A, B) = R^n \times C(A_2, B)$. We consider the condition about all the eigenvalues of $A$ are outside the unit circle. Generally, if $K$ is large enough (i.e. $K = 10$–$30$), $C_K(A, B)$ is fairly approximate to $C(A, B)$.

Correspondingly, let

$$x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}, \quad Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix}.$$  

(11)

Now, we will describe the regulatable region $R_x$ in terms of $C_K(A, B)$ and $W_0$.

**Lemma 1** [17]. Let $V_0 \in R^{m \times r}$ be the unique solution to the linear matrix equation $V_0 - A_2 V_0 P_2$. Then the $K$-step regulatable region $R_x(K)$ is given by

$$R_x(K) = \left\{(x_0, y_0, \omega_0) \in R^n \times R^m \times W_0 : x_0 - V_0 \omega_0 \in C_K(A_2, B_2)\right\}.$$  

(12)

For the first semi-cycle of triangle wave, let $T_1 = T/2$, by carrying out a similarity transformation

$$x(T_1) = A^T x_0 + \sum_{i=0}^{T_1} A^{T_{i+1}} Bu(i) + \sum_{i=0}^{T_1} A^{T_{i+1}} \omega(i)$$

(13)

we get

$$\begin{align*}
\left[ \begin{array}{c}
e_1(T_1) \\ e_2(T_1) \end{array} \right] &= \left[ \begin{array}{c}
C_{A_2} x_0(T_1) - Q_2 \omega(T_1) \\ C_{A_2} x_0(T_1) - Q_2 \omega(T_1) \end{array} \right] \\
&= \left[ \begin{array}{c}
C_{A_2} x_0(T_1) - Q_2 \omega(T_1) \\ C_{A_2} x_0(T_1) - Q_2 \omega(T_1) \end{array} \right]
\end{align*}$$

(14)

Since $Q_2 \omega(T_1)$ is bounded for all $k$ and $A^T_{k} \to \infty$ when $k \to T_1$, $\lim_{k \to T_1} \omega(k) = 0$ stands on

$$x_0 + \sum_{i=0}^{T_1} A_{2}^{-1} B_2 u(i) + \sum_{i=0}^{T_1} A_{2}^{-1} P_2 a = 0.$$  

(15)

Denote $V_0 = - \sum_{i=0}^{T_1} A_{2}^{-1} P_2 a + V_0$ satisfies $V_0 - A_2 V_0 = (A^T - I)^{-1} P_2$. Let $(A^T - I)) = D$, then $D(V_0 - A_2 V_0) = P_2$.

For the second semi-cycle of triangle wave, which can be viewed as the result of half a cycle parallel translation towards the right direction on the time axis

$$\omega(k+1) = \omega(k) - a, \quad \omega(0) = aT_1.$$  

The regulator equation

$$\begin{align*}
\Pi &= A \Pi + BT + P \\
\text{CTI} + Q &= 0 \\
\Pi &= -BG
\end{align*}$$

(16)

Similarly, let $V_0 = - \sum_{i=0}^{T_1} A_{2}^{-1} P_2 (T_1 - i)$, $(A^T - I)) = D$, we get $D(V_0 - A_2 V_0) = P_2$.  

32
4 State feedback controller design

In this section, we will construct a state feedback controller for above system.

**Lemma 2** [18]. Let \( \lambda \in (0, 1) \), for any initial condition \( \tilde{x}_0 \in C_{\lambda}(\lambda^T \mathbf{A}_2, \lambda^T \mathbf{B}_2) \), there exists a state feedback law \( u(k) = h[\tilde{x}(k)] \) such that the solution of \( x(k+1) = A_2 x(k) + B_2 u(k) \) satisfies \( x(k) \in \lambda^T \mathbf{p}_C(\tilde{x}_0) C_i \) and the control signal \( |u(k)|_c \leq \lambda^4 \mathbf{p}_C(\tilde{x}_0) \leq \lambda^k \).

Lemma 2 gives a balance between the state convergence rate and the control of all the initial state in \( C_{\lambda} \), denoted by \( \lambda^k \). The construction of this state feedback controller constructed in [16], based on which, we will construct a revised controller law for regulation problem in this paper.

**Theorem 2.** Assume there exists a matrix \( V_0 \) that satisfies \( D(V_0 \sigma V_0^T) = P_2 \) for every initial pair \( (x_0, \sigma_0) \) in the regulatable region, under the following controller, \( u(k) = h[\tilde{x}(k)] - \lambda^k V_0 \sigma(k) - (1 - \lambda^k) \Pi_1 \sigma(k) \) of the closed-loop system satisfies \( \lim_{k \to \infty} e(k) = 0 \).

**Proof.** Corresponding to (8), we can divide system (1) in to two subsystems

\[
\begin{align*}
    x_1(k+1) &= A_1 x_1(k) + B_1 u(k) + P_1 \sigma(k), \\
    x_2(k+1) &= A_2 x_2(k) + B_2 u(k) + P_2 \sigma(k).
\end{align*}
\]

Denote

\[
\tilde{x}_i(k) = x_i(k) - \lambda^k V_0 \sigma(k) - (1 - \lambda^k) \Pi_1 \sigma(k), \quad i = 1, 2.
\]

By Lemma 1, for \( i = 1, 2 \), we get

\[
\begin{align*}
    \dot{\tilde{x}}_i(k+1) &= A_1 \tilde{x}_i(k) + B_1 h[\tilde{x}_i(k)] - \lambda^k (I - D) P_1 \sigma(k) - \lambda^k V_0 \sigma(k) \\
    &\quad - \lambda^k (I - D) P_2 \sigma(k) - \lambda^k \Pi_1 \sigma(k) \\
    &\quad - \lambda^k \Pi_2 \sigma(k).
\end{align*}
\]

Based on the controller defined in Lemma 2, the state feedback controller can be constructed as:

\[
u(k) = h[\tilde{x}_i(k)] + (1 - \lambda^k) \Pi_2 \sigma(k).
\]

Applying it to the two subsystems

\[
\begin{align*}
    \dot{\tilde{x}}_1(k+1) &= A_1 \tilde{x}_1(k) + B_1 h[\tilde{x}_1(k)] - \lambda^k (I - D) P_1 \sigma(k) - \lambda^k V_0 \sigma(k) - \lambda^k \Pi_1 \sigma(k) \\
    \dot{\tilde{x}}_2(k+1) &= A_2 \tilde{x}_2(k) + B_2 h[\tilde{x}_2(k)] - \lambda^k (I - D) P_2 \sigma(k) - \lambda^k V_0 \sigma(k) - \lambda^k \Pi_2 \sigma(k).
\end{align*}
\]

Then we can get \( \lim_{k \to \infty} \tilde{x}_2(k) = 0 \), \( \| \dot{\tilde{x}}_1(k) \|_2 \leq \lambda^k \) by Lemma 2. Since \( A_1 \) is semi-stable and \( \| \dot{\tilde{x}}_1(k) \|_2 \leq \lambda^k \), \( \tilde{x}_1(k) \) also convergences to the origin.

\[
u(k) = h[\tilde{x}_1(k)] + (1 - \lambda^k) \Pi_2 \sigma(k) \leq 1.
\]

The closed-loop system satisfies \( \lim_{k \to \infty} e(k) = 0 \). Similar controller can be constructed for the second semi-cycle of a triangle cycle.

5 Numerical Examples

**Example 1.** A semi-stable system as follows under the action of square signal \( (T/2=1000) \)

\[
\begin{align*}
    x(k+1) &= 1.4 0 0.2 1.2 \chi(k) + 1 0 0 1 u(k) + 0.1 0 0 0.1 \omega(k) \\
    \omega(k+1) &= 1 0 0 1 \sigma(k) \\
    \epsilon(k) &= 1 0 0 1 \chi(k) - 1 0 0 1 \sigma(k)
\end{align*}
\]

With \( x_0 = [-1.5 -0.8]^T \), \( \omega(0) = [1.5 1.5]^T \), the regulation equation has solutions \( \Pi = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \).

\[
\Gamma = S - A - P = \begin{bmatrix} -0.5 & 0 \\ -0.2 & -0.3 \end{bmatrix}, \quad V = \begin{bmatrix} -0.25 & 0 \\ 0.25 & -0.5 \end{bmatrix}.
\]

Applying the controller provided in [16] \( u(k) = h[\chi(k) - 0.97^2 \sigma(k) + (1-0.97^2) \Pi_1 \sigma(k)] + (1-0.97^2) \Pi_2 \sigma(k) \)

The closed-loop state tracking is shown in Figure 2.

**Example 2.** The following system under the action of triangle signal \( (T=1000) \)

\[
\begin{align*}
    x(k+1) &= 1.4 0 0.2 1.2 \chi(k) + 1 0 0 1 u(k) + 0.1 0 0 0.1 \omega(k) \\
    \omega(k+1) &= 1 0 0 1 \sigma(k) \\
    \epsilon(k) &= 1 0 0 1 \chi(k) - 1 0 0 1 \sigma(k)
\end{align*}
\]

In the first semi-cycle, \( x_0 = [-0.1 -0.01]^T \), \( \omega(0) = [0 0]^T \), \( a = [0.003 0.004]^T \). The regulation equation has solutions
The state feedback controller is applied in the semi-loop state tracking problem. The closed-loop state tracking are plotted in Figure 3.

During the last semi-cycle, \( x_0=[1.5, 2.0]^T \), \( \omega_0=[1.5, 2.0]^T \), \( a=[0.003, 0.004]^T \).

During the last semi-cycle, \( x_0=[1.5, 2.0]^T \), \( \omega_0=[1.5, 2.0]^T \), \( a=[0.003, 0.004]^T \).

The state feedback controller is applied in the semi-loop state tracking problem. The closed-loop state tracking are plotted in Figure 3.

In each cycle period, two different internal mode principles are applied for a semi-cycle respectively, thus \( G \) and \( V \) are got and the state-feedback controller \( u(k) \) are constructed. State tracking in two cycles are shown in Figure 5, with \( x_0=[-0.1, -0.01]^T \), \( \omega_0=[0, 0]^T \), \( a=[0.003, 0.004]^T \).

6 Conclusions

In this brief, we studied the output regulation problem of saturated linear system under the action of nonlinear exosystem. At the equilibrium point, initial state of the plant and exosystems are restricted in a compact set \( W_0 \). The K-Step asymptotically regulatable region \( R_M(K) \) is described by \( W_0 \) and K-Step null controllable region \( c_\infty (A,B) \). Segmented control strategies are applied to external disturbances in the case of square signal and triangle signal. The internal principles for each semi-cycle of the exosystem are given. Controller is constructed based on the state feedback laws proposed. Examples has demonstrated the effectiveness of the proposed control methodology.
